Before the next challenge.

My name

Rodolfo Sierra-Trujillo

A question I want to resolve

Not recorded

Recall. Question. Recalibrate.

What have I completed?

For my previous assignment, I worked on my Unity engine experiment and learned more about how C# works with game development. I practiced creating classes, objects, and methods and learned how they work together. I also worked on my GitHub repository to organize my project files and keep track of my progress.

My previous work:
https://github.com/rsierratrujillo4553-byte/cs110-week11

My explanation of classes, objects, data and actions

From what I understand, a class is like a blueprint that tells the program what an object can do. An object is something created from that class. Fields store information like health, speed, or damage, while properties let the program access or change that information. Methods are the actions that an object can perform.

For example, in C#, I can create a player class with health and speed values and a method that makes the player move. In Unity, the engine uses the script attached to a GameObject to control what happens in the scene. Visual Studio is where I write and edit my code, while Unity is where I can run the game and see the results.

My questions, answers and remaining uncertainty

One question I had was how Unity connects C# scripts to objects in a game. From what I learned, Unity allows me to attach scripts to GameObjects so they can perform actions during gameplay.

Another thing I wanted to understand better was the difference between fields and properties. I learned that fields store data, while properties control how that data can be accessed or changed.

I still want to practice using methods like Start() and Update() because I want to understand when Unity calls them and how they affect the game. I can use my class notes, Unity documentation, and ask my professor if I need help.

My personal GitHub repository URL

https://github.com/rsierratrujillo4553-byte/cs110-week11

Readiness check

I worked on my C# and Unity project and practiced using the engine to understand how scripts work with objects. I also learned how to save my work and use GitHub to keep my project files organized.

My next step is to make sure my latest changes are committed and pushed to GitHub. I also need to open my repository link to confirm that my files are there and can be accessed. I want to continue improving my understanding of C# and Unity so I can use what I learned in future projects.

Replace Chapters with Pipelines

Attention First, Chapter 3, pp. 37–41 (132-page edition).

What I understand from this chapter

What I understand from this chapter is that paying attention to what we are learning is important, especially when using technology and AI. Technology can help us finish tasks faster, but we still need to understand what we are doing instead of depending on it for everything. I think this also connects to game development because I need to understand how my code works before I can create a game that works properly.

My opinion and reasons

I agree that understanding what we are doing is more important than just finishing something quickly. For example, when I was working on my game development projects, I had to learn how scripts, objects, and methods worked together. Sometimes my code wouldn't work, and I had to figure out what was causing the problem. I think taking the time to understand my mistakes helps me become a better programmer instead of just copying code without knowing what it does.

A decision I can apply

For my game idea, I would create a simple three-step route.

Node 1: Story Idea — I would decide what my game is about and what the player needs to accomplish. Before moving forward, I need a clear goal.

Node 2: Player Movement — I would create the player and program basic movement. Before starting, I need the player object and controls ready.

Node 3: Player Action — I would add an action like collecting an item or interacting with something. Before starting, I need the movement working and the object ready to interact with.

After that, I would test everything to make sure the player can complete the actions correctly.

A question or next investigation

One question I still have is how I can make sure my game is easy for players to understand without giving them too many instructions. I want to test whether players can figure out the controls and objectives on their own. My next step would be to create a small playable section and see if someone can complete it without needing help. I think this would help me understand how to make better games in the future.

Design for the Attention Economy

Attention First, Chapter 6, pp. 53–58 (132-page edition).

What I understand from this chapter

What I understand from this chapter is that attention is important when learning and working on projects. Sometimes distractions or having too many things happening at once can make it harder to focus. I think having a clear plan and organizing my work can help me understand what I am doing instead of rushing through everything. This connects to programming because I need to pay attention to my code and understand how everything works together.

My opinion and reasons

I agree that distractions can affect how well we work and learn. When I was working on my Unity and C# projects, I sometimes had to switch between my code, the game engine, and instructions. This made it harder to focus on one problem at a time. I think organizing my work into smaller steps would help me stay focused and make fewer mistakes. It would also make it easier to figure out what went wrong when something doesn't work.

A decision I can apply

One attention leak in my previous work was switching between Visual Studio, Unity, and my assignment instructions too often. To fix this, I would organize my work into smaller steps and focus on one task before moving to another. For example, I would write my code first, then test it in Unity, and finally check my instructions to make sure I completed everything. I would know this change is helping if I finish tasks with fewer mistakes and spend less time trying to figure out where I left off.

A question or next investigation

One question I have is how I can stay focused when working on bigger programming projects that require multiple tools. I want to test whether breaking my work into smaller tasks will help me finish things more efficiently. For my next project, I would try completing one feature at a time and testing it before moving on. I would compare how many mistakes I make and how long it takes me to finish each task.

Identity and the Creator Loop

Attention First, Chapter 7, pp. 61–69 (132-page edition).

What I understand from this chapter

What I understand from this chapter is that our actions and decisions show what kind of standards we have for ourselves. It is easy to say that we want to do good work, but what really matters is how we respond when something goes wrong. I think making mistakes is part of learning, but we also need to take responsibility and try to improve. This connects to programming because not everything is going to work the first time, and I need to be willing to fix my mistakes instead of giving up.

My opinion and reasons

I agree that our actions are more important than just saying what we are going to do. For example, when I was working on my game development projects, I ran into problems with my code that I didn't understand at first. Instead of leaving those problems alone, I kept testing different solutions until I figured out what was wrong. I think this shows that I am willing to learn from my mistakes and put effort into improving my work. I also believe that being consistent is important because small improvements can lead to better results over time.

A decision I can apply

One mistake I made in my previous Godot project was when some enemies were not shooting correctly. My response was to go back through my code and figure out why the normal enemies were not working like the fast scouts. This showed me that I need to be patient and take responsibility for fixing problems in my projects.

One standard I want to protect is making sure my code works correctly before moving on to another feature. A small action I can repeat is testing each new feature after I add it. This will help me catch mistakes earlier and keep my projects organized.

A question or next investigation

One question I still have is how I can become more consistent when working on bigger programming projects. Sometimes I get focused on adding new features before checking everything I already made. For my next project, I want to test each feature before moving forward and keep track of any problems I find. I would know this is helping if I spend less time fixing older mistakes and my projects run more smoothly.

Designing Your Teams and Tools

Attention First, Chapter 8, pp. 71–74 (132-page edition).

What I understand from this chapter

What I understand from this chapter is that everyone has different skills and responsibilities when working on a project. It is important to know what you can contribute, what you still need to learn, and which tools will actually help you accomplish your goals. I also understand that doing good work is not just about finishing your own part, but also making sure everyone is working toward the same goal. This connects to programming because creating a game requires both technical skills and good teamwork.

My opinion and reasons

I agree that having the right skills and knowing your responsibilities can make a project more successful. For example, when I was working on my C# and Unity assignments, I had to understand how the code worked before I could get everything running correctly. I also learned that having the right tools makes a difference, but the tools won't automatically solve every problem. I still need to understand what I am doing and be willing to learn new things. I think this is important because I want to create my own video games in the future.

A decision I can apply

One thing I can contribute to a team is my experience with programming and game development. I have worked with C#, Unity, and Godot, and I can help with coding and testing features. One capability I still need to improve is organizing larger projects and communicating with teammates.

A tool I would use is GitHub because it helps keep track of changes and allows team members to share their work. Protecting craft means making sure my code is organized, tested, and working correctly. Coordinating direction means making sure everyone understands the project's goals and what they need to do.

One responsibility I would accept is testing the game's features and making sure they work before we move forward.

A question or next investigation

One question I still have is how a team can balance everyone working on their own tasks while making sure the whole project stays organized. For my next group project, I want to try using GitHub to keep track of everyone's progress and make sure our work fits together. I would know this is helping if we have fewer problems combining our work and everyone understands what they are responsible for.

The Human Operating System

Attention First, Chapter 11, pp. 93–103 (132-page edition).

What I understand from this chapter

What I understand from this chapter is that we should put our time and effort into something that has a meaningful purpose. It is important to have a goal, but we also need to think about the choices we make to reach that goal. I think exploring different ideas is good because it helps us learn, but we also need to make sure our decisions are actually helping us improve. This connects to game development because I need to know what kind of game I want to create and why I want to create it.

My opinion and reasons

I agree that having a clear purpose can help us make better decisions. For example, one of my goals is to create my own video games. When I started working with Godot, I wanted to learn how to make a space shooter. I had to decide what features I wanted to add and which ones were more important. Instead of trying to make everything at once, I worked on movement, shooting, enemies, and other features one at a time. I think having a clear goal helped me stay focused and make progress.

A decision I can apply

One mission that is worth my effort is learning how to create my own video games that people can enjoy. I want to improve my programming skills and eventually create a complete game. One alternative I considered was using Unity instead of Godot, but I chose Godot because I wanted to start with something that would help me learn 2D game development.

I will explore different gameplay ideas, enemy types, and features freely because I want to be creative. However, I will verify that my code works correctly and that the game is actually playable. I will reconsider my decisions if a feature becomes too difficult to manage or doesn't improve the game. My goal is to keep learning while making steady progress.

A question or next investigation

One question I still have is how I can tell when an idea is worth continuing or when I should try something different. Sometimes I get excited about adding new features to my games, but I also need to think about whether those features actually make the game better. For my next project, I want to test new ideas before spending too much time on them. I would know this is helping if I can make better decisions about which features to keep and which ones need to be changed.

Bring something to the summit.

The connection across the readings

What I learned from these five readings is that having a purpose, staying focused, working with others, and using the right tools are all important when trying to accomplish a goal. One thing that stood out to me is that technology can help us, but we still need to understand what we are doing and take responsibility for our work. I also learned that mistakes are part of improving and that our actions show how serious we are about our goals.

This connects to my experience with programming because I have worked on projects where I had to solve problems, learn new skills, and make decisions about what to do next. These readings helped me understand that I should focus on creating games that people can enjoy instead of just adding features without a purpose. I also want to become better at communicating with teammates and organizing my work so everyone can contribute.

Evidence I am ready to show

One thing I can show a future teammate is my experience working with C#, Unity, and Godot. I have created a 2D space shooter in Godot that includes player movement, shooting, enemies, health, a score system, and weapon upgrades. This shows that I can take an idea and turn it into something that actually works. I can also show my previous CS110 assignments and GitHub repository to demonstrate how I organize my projects and track my progress.

One thing I still need to improve is working on larger projects with other people. I want to learn more about organizing code, using GitHub with a team, and making sure everyone's work fits together correctly. My goal is to continue improving my programming skills so I can eventually create my own complete video games.

My board in words

The mission sits at the center, written as a one-sentence outcome: a finished, tested player action. Three connected nodes run from left to right toward it, labeled Orientation, Setup, and Story and action, and each node has a note about what must be ready before it begins (Ch. 3).

Above the nodes, I’ve placed two small icons for attention leaks I’m watching for, unclear instructions and switching between tools (Ch. 6).

Below the nodes sit the people and tools that support the mission. Each
person has a label showing what they contribute, master (craft) or chief (direction), and each tool has a short reason for being there (Ch. 8).

On the right, near the finish line, is a small box for my standard and repeatable action (the five-minute final check, Ch. 7).

At the bottom is a “reconsider” checkpoint with a date, plus a separate “explore freely” area and a “verify” area (Ch. 11).

Arrows run from the mission to each node, from each node to the next, and from the checkpoint back to the nodes, to show that I adjust after testing

Choose where you want to go.

My direction

Join a lead

The mission I want to explore

Our game is for players who enjoy mystery, exploration, and psychological puzzle games that make them think. The story follows a character named NaN, who is trapped inside the mind of someone in a coma. The player starts in complete darkness and slowly discovers the world by exploring and interacting with objects connected to memories. I think this would be interesting because players would have to figure out what is happening without the game telling them everything. Our goal is to create a unique experience where the player uncovers the story while bringing the world back to life.

My pitch

The game follows NaN, which stands for No Assigned Name. NaN starts as a small point of light in a dark world connected to the memories of someone in a coma. Players find objects called Stimuli that help bring the
world back. There is also an entity called Static that changes based on how the player acts. The story moves through The Dark, The Ward, The Deep, and a final moment involving a door labeled WAKE UP. I think the
mystery and discovery are what can make this game stand out.

Conversations and decisions

I was part of the conversations about combining teams and contributed gaming ideas. The group discussed using Unity, C#, Visual Studio, and a 3D PC game for the first version. We also discussed keeping the scope small, with the opening and a few rooms instead of the entire game. Some details, including exactly what Stimuli do and the full backstory, still need to be decided.

Agree on the work.

Team name / solo mission

DufAyzO - working together on StimuLye.

Agreed lead / my name if solo

Lexxie is the team lead.

Accepted members and contributions

Lexxie leads the project and works on the core concept and Unity/C# prototype. David coordinates and documents the work. Paulina helps manage requirements and deadlines. Sam supports the team with ideas and other tasks. I contribute gaming experience and help with brainstorming. Leah has a role still being defined; Vin and Nico were listed as pending in the original plan. AI is listed as a support tool for notes and brainstorming.

How the literature strengthens this team

One important thing I took from our class discussion is that a team needs to agree on its goal before everyone
starts working separately. For this project, it makes sense to understand the story and the basic player experience before adding more features. Having clear roles should also help us avoid confusion about who is
doing what.

Communication and check-in plan

We plan to communicate through the CS110 Discord and our team group chat. Notes and whiteboard pictures
can go in Discord, while project files and code belong on GitHub. We should share updates before class and compare our progress during our check-in.

Team GitHub URL, or Working solo

https://github.com/Lexicon-Lexxie/CS110-Awayzo/tree/main

Make the Attention Accord.

Purpose and smallest playable result

The player controls NaN and tries to restore a dark world by exploring and interacting with Stimuli. The smallest playable version should start with a black screen, reveal part of the room after mouse movement, and
let the player approach an orb. Interacting with it should make an object or part of the room more visible. That
gives the player an action and a clear result without needing a long tutorial.

My attention promise

My focus question is: Can a new player understand that moving and exploring changes the world without being told exactly what to do? I want to observe a short playtest and write down where the player gets confused or interested. I can share that feedback with the team so we know what needs to change.

Time and dependency plan

The team first needs a working opening scene. After that, we need to agree on the behavior of the Stimuli before testing the full interaction. I can give feedback on the opening first and then test the orb interaction once it is available. If a feature is not ready, we can still test it with simple placeholder objects.

Board explanation and contributors

Our main gameplay chain is: NaN explores the dark, notices an orb, moves closer, interacts with it, and sees
the room gain detail. The board also connects team responsibilities, tools, and decisions that are still open. David documented the class whiteboard, and I contributed to the team discussions and ideas.

Translate the mission into code.

My story-to-code map

One important object is a Stimulus orb. In Unity, it could use a Stimulus component with a reveal distance, a
reference to the object it turns into, and a flag showing whether it has already been restored. When the player
gets close, the orb can begin changing. When the player interacts, a Restore() method can reveal the object and tell the room to add detail. The player should immediately see a difference.

What I am borrowing and why

The original team plan uses Unity features such as Vector3.Distance to check how close the player is to an orb and built-in input handling for interactions. These are features of Unity rather than extra downloaded packages. From a player perspective, this helps make the orb react naturally as someone approaches it.

Object lifetime and responsibility

The orbs can be placed in the scene ahead of time. After an orb is restored, it should stop acting like an active
orb so the same interaction does not happen over and over. The team can check the Unity Hierarchy and use
debugging messages to make sure the interaction only happens once.

Make one moment playable.

What I expect to happen

I expect the player to begin in darkness, move the mouse to reveal the environment, approach a glowing orb,
and interact with it to restore some detail to the room.
